

chapter 7

Rotational Dynamics

2. Kinetic Energy of Rigid Body

The rigid body of mass M and radius R . The moment of inertia about center of mass is I_{cm} . The velocity of center of mass is v_{cm} and angular velocity about center of mass is ω , then kinetic

energy is $T = \frac{1}{2} Mv_{cm}^2 + \frac{1}{2} I_{cm} \omega^2$

Example: A sphere of mass M and radius R having velocity of center of mass v_0 . As friction of surface is enough so that sphere Achieving condition of Rolling without Slipping. Find the kinetic energy of sphere.

Solution: $T = \frac{1}{2} Mv_{cm}^2 + \frac{1}{2} I_{cm} \omega^2 = \frac{1}{2} Mv_0^2 + \frac{1}{2} \frac{2}{5} MR^2 \omega^2$

Rolling without slipping, $v_{c.m} = \omega R$ $\omega = \frac{v_0}{R}$ $\frac{1}{2} Mv_0^2 + \frac{1}{2} \frac{2}{5} MR^2 \frac{v_0^2}{R^2} = \frac{7}{10} Mv_0^2$

Example: A rod of length l is pivoted at one of its end. If rod is constrained to move in $y-z$ plane, then

- (a) find the total energy of system
- (b) find angular frequency for small oscillation.

Solution: (a) $T = \frac{1}{2}M(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}I_{cm}\omega^2$

$$x = \frac{l}{2} \sin \theta, \Rightarrow \dot{x} = \frac{l}{2} \cos \theta \dot{\theta} \quad y = \frac{l}{2} \cos \theta \Rightarrow \dot{y} = -\frac{l}{2} \sin \theta \dot{\theta}$$

Kinetic energy $T = \frac{1}{2} \frac{l^2}{4} \dot{\theta}^2 + \frac{1}{2} \frac{Ml^2}{12} \dot{\theta}^2 = \frac{Ml^2}{6} \dot{\theta}^2$

Potential energy V is given by $V(\theta) = -\frac{Mgl \cos \theta}{2}$

$$E = T + V \Rightarrow E = \frac{1}{2} \left(\frac{Ml^2}{3} \right) \dot{\theta}^2 - \frac{Mgl}{2} \cos \theta$$

(b) Hence, energy is conserved $\frac{dE}{dt} = 0 \Rightarrow E = \left(\frac{Ml^2}{3} \right) \dot{\theta} \ddot{\theta} + \frac{Mgl}{2} \sin \theta \dot{\theta} = 0 \Rightarrow \left(\frac{l}{3} \right) \ddot{\theta} + \frac{g}{2} \sin \theta = 0$

for small oscillation, $\sin \theta = \theta$, so $\left(\frac{l}{3} \right) \ddot{\theta} + \frac{g}{2} \theta = 0 \Rightarrow \omega = \sqrt{\frac{3g}{2l}}$

Example: A rod of mass m and length l is suspended from two mass less vertical springs with a spring constants k_1 and k_2 . If x_1 and x_2 be the displacements from equilibrium position of the two ends of the rod, find the kinetic energy of system.

Solution: $T = \frac{1}{2} Mv_{c.m}^2 + \frac{1}{2} I_{c.m} \omega^2 = \frac{1}{2} m \left(\frac{\dot{x}_1 + \dot{x}_2}{2} \right)^2 + \frac{1}{2} \frac{ml^2}{12} \dot{\theta}^2$

$\sin \theta = \frac{x_2 - x_1}{l}$ for small oscillation $\theta = \frac{x_2 - x_1}{l} \Rightarrow \dot{\theta} = \frac{\dot{x}_2 - \dot{x}_1}{l}$

(keep in mind that there is not pure rotation case)

$$T = \frac{1}{2} m \left(\frac{\dot{x}_1 + \dot{x}_2}{2} \right)^2 + \frac{1}{2} \frac{ml^2}{12} \left(\frac{\dot{x}_1 - \dot{x}_2}{l} \right)^2 \Rightarrow T = \frac{m}{6} (\dot{x}_1^2 + \dot{x}_1 \dot{x}_2 + \dot{x}_2^2)$$

Example: A stick of length l and mass M initially upright on a frictionless table, starts falling. The problem is to find the speed of the center of mass as a function of position.

Solution: The key lies in realizing that since there are no horizontal forces, the center of mass must fall straight down. Since we must find velocity as a function of position, it is natural to apply energy methods.

The sketch shows the stick after it has rotated through angle θ and the center of mass has fallen distance y . The total

energy at rest is $E = K_0 + U_0 = \frac{Mgl}{2}$

The kinetic energy at a later time is $K = \frac{1}{2} I_{cm} \dot{\theta}^2 + \frac{1}{2} M \dot{y}^2$

and the corresponding potential energy is $U = Mg \left(\frac{l}{2} - y \right)$.

Since, there are no dissipative forces, mechanical energy is conserved and

$$K + U = K_0 + U_0 = \frac{Mgl}{2}.$$

Hence, $\frac{1}{2} M \dot{y}^2 + \frac{1}{2} I_{cm} \dot{\theta}^2 + Mg \left(\frac{l}{2} - y \right) = Mg \frac{l}{2}$.

We can eliminate θ by turning to the constraint equation. From the sketch we see that $y = \frac{l}{2} (1 - \cos \theta)$. Hence, $\dot{y} = \frac{l}{2} \sin \theta \dot{\theta}$ and $\dot{\theta} = \frac{2}{l \sin \theta} \dot{y}$ Since, $I_{cm} = M \left(\frac{l^2}{12} \right)$, we obtain

$$\frac{1}{2} M \dot{y}^2 + \frac{1}{2} M \frac{l^2}{12} \left(\frac{2}{l \sin \theta} \right)^2 \dot{y}^2 + Mg \left(\frac{l}{2} - y \right) = Mg \frac{l}{2}$$

or $\dot{y}^2 = \frac{2gy}{\left[1 + \frac{1}{3 \sin^2 \theta} \right]} \Rightarrow \dot{y} = \left[\frac{6gy \sin^2 \theta}{3 \sin^2 \theta + 1} \right]^{1/2}$, where $y = \frac{l}{2} (1 - \cos \theta)$
